hypothesis	supported
Annual growth is jointly influenced by water, temperature, DBH, and time.	
Water and temperature additively influence annual growth,	36 / 46 species-site combinations
...typically over different time windows .	9 / 10 sites
Drought limits tree growth, but the response to water is nonlinear.	
The time window over which water influences growth is often $\geq$ 9 months.	5 / 10 sites
Growth respones to precipitation are predominantly positive,	34 / ?? Species-site combinations
...but positive responses decelerate or decline at high precipitation.	32 / 34 species-site combinations with positive first-order terms
Temperature has predominantly negative, nonlinear effects on growth.	
The time window over which T influences growth rarely exceeds 3 months.	9 / 10 sites
Annual growth responds more strongly to T_{max} or PET than to T_{min}.	8 / 10 sites
Growth respones to T are predominantly negative, particularly at higher T.	
However, there are cases where growth increases under warmer T.	
DBH	
Ring width increment (RW) declines with DBH for trees established in the open....	
...but increases with DBH for trees established in the understory.	
Basal area increment (BAI) increases to a peak at intermediate DBH and then declines.	
Biomass increment (ΔAGB) increases to a peak at intermediate DBH and then declines.	98 percent of species-site
